# 5-1 Discussion: Incidents of Hacking and Response

Listen

Possible Points: **22**

Throughout this module, you learned that common security vulnerabilities are often discovered during the software reverse engineering process. Unfortunately, this is not always the case. Many hackers find vulnerabilities in software before a reverse engineering process has begun. Software hacking is a global problem that often impacts organizations that hold extensive or sensitive data on customers, employees, or others. Before participating in this discussion, research an example of a company, government agency, or organization that has been victimized by hackers.

In your initial post, include a link to a citation that references the incident, and explain what happened in the incident. Be sure to include answers to questions such as the following:

- Which company was targeted?
- What data was stolen, lost, or corrupted?
- How was the incident detected?
- What factors led to the vulnerability? How were they exploited by hackers?

Next, discuss the response and lessons learned by answering the following questions:

- How did the organization respond to the incident? What steps were taken?
- What lessons can be learned from this incident? How can security be improved? For instance, should additional layers of security be added?
- How can reverse engineering be used to identify or address the vulnerability?

After your initial post, respond to at least two classmates by reviewing and commenting on their conclusions.

Then, discuss the following:

- What would you add to their claims?
- Are there other security measures that could be taken?
- What more can be learned from the incident described?
- Are their additional ways to perform reverse engineering to prevent a similar incident from occurring in the future?

To complete this assignment, review the Discussion Rubric.
